## 1 Set-up

```
# clear
rm(list=ls())

# load libraries
library(tidyverse)
```

```
library(brms)
library(glmmTMB)
```

## 2 Annual plant parameters

### 2.1 events

1. seeds germinate or don't
  - a. germination depends on the amount of litter
2. seeds that don't germinate (i.e., dormant) must survive to the next spring (1 year)
3. germinants grow and produce more seeds
  - a. growth depends on competition
4. newly produced seeds must survive to the next spring (overwinter)

### 2.2 annual germination in the absence of litter

*Microstegium vimineum* germination from 200 planted seeds and an estimated number of background seeds based on a neighboring subplot in plots with litter removed. Methods: field\_litter\_experiment\_2018.docx.

```
# import model
load("../big-oaks-field-experiment-2018-2019/microstegium-bipolaris/output/mv_germination_litter_mod

# extract fixed effects
A_germ_est <- fixef(mv_germ_litter_mod) %>%
  as_tibble() %>%
  mutate(parm = c("max_germ_autoclaved", "max_germ_live", "alpha_autoclaved", "alpha_live"))

# select the no-litter values
g.A_parms <- filter(A_germ_est, parm == "max_germ_live") %>%
  mutate(Estimate = Estimate / 200,
         Q2.5 = Q2.5 / 200,
         Q97.5 = Q97.5 / 200)

# check
g.A_parms$Estimate

## [1] 0.6017131
```

### 2.3 reduced annual germination due to litter

Same experiment as above except also using plots with litter added

```
# select the no-litter values
beta.A_parms <- filter(A_germ_est, parm == "alpha_live")

beta.A_parms$Estimate

## [1] 1.027311
```

## 2.4 survival of dormant annual seeds

We used the survival data collected by Redwood et al. (2018) in November 2011 (buried for one year). Some of these seeds would have germinated had they been exposed to a germination test earlier in the year. Scroll down to seed viability for final survival value.

```
# load extracted figure data
rw18_2a <- read_csv("../data/Redwood_2018_Fig2A.csv")
```

```
## Parsed with column specification:
## cols(
##   month = col_character(),
##   surv = col_double()
## )
```

```
# select month
(s.A0 <- filter(rw18_2a, month == "Nov 11") %>%
  select(surv) %>%
  round(digits = 1) / 100)
```

```
##   surv
## 1 0.05
```

## 2.5 survival of annual seedlings

Survival is not clearly affected by density, so the raw data mean is used.

```
summer_surv <- read_csv("../..big-oaks-field-experiment-2018-2019/microstegium-bipolaris/intermediate-")
```

```
## Parsed with column specification:
## cols(
##   site = col_character(),
##   plot = col_double(),
##   treatment = col_character(),
##   ID = col_character(),
##   focal = col_double(),
##   plant_type = col_character(),
##   survival = col_double(),
##   flag = col_character(),
##   background = col_character(),
##   background_sp = col_character(),
##   background_density = col_double(),
##   density_level = col_character()
## )
```

```
(h.A <- summer_surv %>%
  filter(plant_type == "Mv seedling" & treatment == "water") %>%
  summarise(h.A = mean(survival)))
```

```
## # A tibble: 1 x 1
##   h.A
##   <dbl>
## 1 0.948
```

## 2.6 growth of annual in the absence of competition

We oven-dried and weighed individual *M. vimineum* at the end of the growing season in 2019. Methods: field\_density\_experiment\_2018\_2019.docx

```
# import model
load("../..big-oaks-field-experiment-2018-2019/microstegium-bipolaris/output/mv_biomass_combined_backg

# extract fixed effects
A_bio_est <- fixef(mv_bio_mod) %>%
  as_tibble() %>%
  mutate(parm = c("max_bio_fungicide", "max_bio_water", "alpha_EvA_fungicide", "alpha_EvA_water", "alpha_EvS_fungicide", "alpha_EvS_water", "alpha_MvS_fungicide", "alpha_MvS_water"),
         treatment = rep(c("fungicide", "water"), 4),
         parm_type = c(rep("max_bio", 2), rep("alpha", 6)))

# select intercept with disease suppression
v.A_parms <- filter(A_bio_est, treatment == "water" & parm_type == "max_bio")

# check
v.A_parms$Estimate

## [1] 26.46661
```

## 2.7 reduction in annual growth due to competition

```
# subset data
A_alpha_dat <- filter(A_bio_est, treatment == "water" & parm_type == "alpha")

# print values
A_alpha_dat %>%
  select(parm, Estimate)

## # A tibble: 3 x 2
##   parm          Estimate
##   <chr>          <dbl>
## 1 alpha_EvA_water  0.134
## 2 alpha_EvS_water  0.0779
## 3 alpha_MvS_water  0.0864
```

## 2.8 conversion from annual biomass to seed production

```
# import model
load("../..big-oaks-field-experiment-2018-2019/microstegium-bipolaris/output/mv_seeds_per_biomass_model

# look at coefficients

# manually add up relevant coefficients (biomass, year2:biomass)
(y.A0 <- 10.264 + 74.136)

## [1] 84.4
```

## 2.9 annual seed viability

Using Fig. 2A from Redwood et al. (2018), 40% of the seeds survive from December to April. Survival is the sum of germinated and viable non-germinated seeds. This parameter would only be applied to newly produced seeds (i.e., multiply  $y.A$  by  $w.A$ ). Note that empirical values for seed bank survival include both viability and longer term survival. We divide by viability to get the new survival value because these will be effectively multiplied again in the model.

```
include_graphics("../data/lit_figures/Redwood_2018_Fig2A.jpg")
```

```
w.A <- 0.4
(y.A <- y.A0 * w.A)
```

```
## [1] 33.76
```

```
(s.A <- s.A0 / w.A)
```

```
##      surv
## 1 0.125
```

### 3 Annual litter parameters

#### 3.1 events

1. newly formed biomass loses water and slightly decomposes over the winter
2. litter decomposes each year

#### 3.2 conversion from annual biomass to litter

We measured biomass from the same area in the same plots with adjacent samples in October 2018 and April 2019. Note: source code needs to be located, but I'm fairly confident this value is correct.

```
# import data
A_lit_dat <- read_csv("../big-oaks-field-experiment-2018-2019/microstegium-bipolaris/intermediate-da

## Parsed with column specification:
## cols(
##   .default = col_double(),
##   entry = col_character(),
##   sample_ID = col_character(),
##   site = col_character(),
##   treatment = col_character(),
##   processing_notes = col_character(),
##   flag = col_character(),
##   background = col_character(),
##   background_sp = col_character(),
```

```
## density_level = col_character()
## )

## See spec(...) for full column specifications.
# take average of litter/biomass measurements
(a <- A_lit_dat %>%
  filter(treatment == "water") %>%
  summarise(a = mean(litter_conversion, na.rm = T)))

## # A tibble: 1 x 1
##       a
##   <dbl>
## 1  1.11

# a gain in biomass does not make sense
a <- 1
```

### 3.3 annual litter decomposition

We used the mass remaining in the litter bags from DeMeester and Richter (2010) after one year in the field.

```
# import data
dr10_3 <- read_csv("../data/DeMeester_2010_Fig3.csv")

## Parsed with column specification:
## cols(
##   days = col_double(),
##   mass.prop = col_double()
## )

# figure
include_graphics("../data/lit_figures/DeMeester_2010_Fig3.jpg")
```

```
# extract parameters
(b <- 1 - filter(dr10_3, days == max(dr10_3$days)) %>% select(mass.prop)/100)

## mass.prop
```

```
## 1      0.67
```

## 4 Perennial plant parameters

### 4.1 events

1. seeds germinate or don't
  - a. germination depends on the amount of litter
2. seeds that don't germinate (i.e., dormant) must survive to the next spring (1 year)
3. germinants grow and produce more seeds
  - a. growth depends on competition
4. newly produced seeds must survive to the next spring (overwinter)
5. seedlings that survive to the next spring become adults (1 year)
6. adults also produce seeds, which depends on competition

### 4.2 perennial germination in the absence of litter

*Elymus virginicus* germination from 50 planted seeds in field plots with litter removed and in greenhouse pots. Methods: field\_litter\_experiment\_2019.docx, REU 2018 manuscript.

```
# import data
S_field_germ_dat <- read_csv("../big-oaks-field-experiment-2018-2019/microstegium-bipolaris/data/botl
